Obstructive hydrocephalus due to cavernous dilation of Virchow-Robin spaces

A 10-year-old girl presented with a 4-month history of headache and with a normal examination. MRI showed a multi-cyst mesencephalic lesion isointense relative to CSF on all sequences; there was mass effect on the aqueduct with obstructive hydrocephalus (figure). Infections, tumors, and epidermoid cyst were considered, but the characteristic location along the path of a penetrating vessel and magnetic resonance appearance is virtually pathognomonic of cavernous dilation of Virchow-Robin spaces.\(^1\)\(^2\) She received a ventriculoperitoneal shunt with prompt improvement of the headache and the hydrocephalus. Clinical and imaging follow-up examinations revealed no change.

(A–E) Axial T2, coronal fluid-attenuated inversion recovery, sagittal T1 precontrast and postcontrast, and diffusion-weighted MRI show multiple and confluent cyst-like lesions in the right thalamo-mesencephalic region isointense to CSF, causing obliteration of the aqueduct and no diffusion restriction. (F) Coronal CT reconstruction after ventriculoperitoneal shunt with resolution of hydrocephalus.
