Pseudo-abnormal DaTscan findings in meningioma-induced parkinsonism

A 71-year-old man presented with a 6-month history of rest tremor and slowness in his left hand. Apart from mild left parkinsonism, neurologic examination was unremarkable. Because response to L-dopa, up to 600 mg/d, was lacking, $^{[123]I}$FP-CIT ($^{[123]I}$-N-ω-fluoropropyl-2β-carbomethoxy-3β-[4-iodophenyl]nortropane) SPECT was prescribed with unexpected results: transverse and coronal slices showed the right striatum to be moved upward and medially, suggesting a structural compression rather than degenerative damage (figure). Brain MRI revealed the presence of a frontal meningioma with mild surrounding edema. Caution is required when interpreting DaTscan findings, and morphologic imaging should always be performed first.

AUTHOR CONTRIBUTIONS
Dr. R. Erro: acquisition of data, analysis and interpretation, writing the first draft. Dr. S. Pappatà: acquisition of data, analysis and interpretation, critical revision of the manuscript for important intellectual content. Dr. M. Picillo, Dr. M. Rocco, and Dr. G. Santangelo: acquisition of data. Prof. P. Barone: interpretation of data, critical revision of the manuscript for important intellectual content. Dr. C. Vitale: analysis and interpretation of data, critical revision of the manuscript for important intellectual content.

STUDY FUNDING
No targeted funding reported.

DISCLOSURE
The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.
