Dyke-Davidoff-Masson syndrome in adulthood
A 50-year diagnostic delay

A 54-year-old woman was seen due to weakness and gait difficulty. Physical examination revealed spasticity (Ashworth 2–3), weakness (3/5), hyperactive deep tendon reflexes on the right side, and facial asymmetry. MRI of the brain was consistent with Dyke-Davidoff-Masson Syndrome (DDMS) (figure). DDMS ensues due to an insult to the developing brain, characterized by cerebral hemiatrophy, contralateral hemiparesis, unilateral thickening of the skull, widening paranasal sinuses, fascial asymmetry, and mental retardation. Diagnosis of DDMS is very uncommon in adulthood.1,2 This unusual presentation suggests that a late diagnosis of DDMS may occur.

Vedat Biçici, MD, Timur Ekiz, MD, İzzet Bingöl, MD, Cem Hatipoglu, MD

From Ankara Atatürk Training and Research Hospital (V.B., I.B.) and Ankara Physical Medicine and Rehabilitation Training and Research Hospital (T.E., C.H.), Turkey.

Author contributions: Dr. Biçici: acquisition of data, study concept or design, drafting/revising the manuscript, accepts responsibility for conduct of research and final approval. Dr. Ekiz: acquisition of data, study concept or design, drafting/revising the manuscript, accepts responsibility for conduct of research and final approval. Dr. Hatipoglu: acquisition of data, design, drafting/revising the manuscript, accepts responsibility for conduct of research and final approval. Dr. Bingöl: drafting/revising the manuscript, study concept or design, accepts responsibility for conduct of research and final approval.

Study funding: No targeted funding reported.

Disclosure: The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.
