Teaching NeuroImages: Spontaneous resolution of a giant intracranial arachnoid cyst

A giant arachnoid cyst (6 × 8 × 11 cm) of left middle cranial fossa was found incidentally in a 3-year-old boy with head MRI examination for increased head circumference (figure 1). Surgical intervention was refused by his parents since the boy was asymptomatic, and the patient was followed up. Repeated MRI performed 2 years later revealed disappearance of the cyst, and the compressed brain tissue had significantly re-expanded (figure 2). There was no history of head trauma or stroke. The spontaneous resolution of a giant intracranial arachnoid cyst is extremely rare and the mechanism is not clear.1,2

AUTHOR CONTRIBUTIONS
Zhiyong Liu provided pictures of the patient and drafted the manuscript. Jin Li revised the manuscript. Jianguo Xu was responsible for the study concept and revised the manuscript for intellectual content.

STUDY FUNDING
No targeted funding reported.

DISCLOSURE
The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.

REFERENCES

From the Department of Neurosurgery, West-China Hospital, Sichuan University, China.
Axial T2-weighted imaging (A, B), axial T1-weighted imaging (D, E), and coronal FLAIR image (C, F) indicate the disappearance of the cyst and the compressed brain tissue has re-expanded into the seemingly normal left temporal lobe (arrow). Axial T1-weighted imaging (E) reveals that there was residual cyst wall (arrow).
