Bilateral occipital strokes from an atherosclerotic trigeminal artery

A 58-year-old man with coronary disease presented with headache, confusion, and vision loss. On examination, he had retrograde and anterograde amnesia, superior homonymous quadrantanopias, and could not identify colors. MRI showed bilateral occipital infarcts involving the parahippocampal and lingual gyri (figure 1). CT angiography revealed a hypoplastic vertebrobasilar circulation, with a persistent right trigeminal artery supplying the rostral basilar artery (figure 2). Persistent fetal arteries may increase risk of atherogenesis due to increased turbulence. A rare cortical syndrome, new-onset achromatopsia with amnesia should provoke concern for top of the basilar syndrome. In this case, fetal artery intracranial atherosclerosis resulted in a "top of the trigeminal" syndrome.

Eliza C. Miller, MD, Joshua Z. Willey, MD, MSc
From the Department of Neurology, College of Physicians and Surgeons, Columbia University, New York, NY.

Author contributions: Dr. Miller: drafting manuscript, designing figures. Dr. Willey: critically reviewing and revising manuscript for intellectual content.

Study funding: No targeted funding reported.

Disclosure: E. Miller reports no disclosures relevant to the manuscript. J. Willey received funds from the NIH (NINDS K23 073104) and is a consultant for Heartware Incorporated. Go to Neurology.org for full disclosures.

Correspondence to Dr. Miller: ecm2137@cumc.columbia.edu

Coronal sections through the rostral basilar artery demonstrate supply by a persistent right trigeminal artery (A, B, arrows). There is severe intracranial atherosclerosis, with dilated and tortuous carotid arteries. Axial section (C) shows severe stenosis at the origin of the trigemino-basilar system (arrow).
